Subject: Question: SPF

I have a mail relay/redirect service that collects all my incoming email over SMTP from the internet, spools it and sends it to my home mail server on a custom SMTP port. When nospamtoday receives the mail it sees the mail coming from my redirect service, rather than the internet host of the sender's mail server. This violates the SPF record check and the SPF check fails and adds to the spam score.

I've read that mail services like the one I use will be working on implimenting a feature to fix this issue (can't remember what its called), but I was just wondering if any other users ran into this and what they did to work around it. Sending mail for my domains is no problem, I have SPF setup for all my hosts correctly, this issue only happens when receiving mail from senders who use SPF.
