Hi

NST receives the correct IP address from the sender but transforms it to the servers IP address (mostly 192.168.1.x) before transferring the mail to the mail-server. Why do you do that?

Is it not useful to keep the senders address because NST works like a proxy and not like a MTA.

In my mail-server i have additional antispam-tests based on the ip-address which i cannot use at the moment.

Thanks for your answer

KurtSch

besser.
