Hello,

Which version of NST supports a multi domain and multi mail server's environment?

What I need is a machine running NST that can forward mail to the appropriate mail server regarding the domain name.

Example:

mail from \*@domainAAA.com > 192.168.0.1:25

mail from \*@domainBBB.com > 192.168.0.2:25

Thanks

This feature is supported by all NST editions.

All you have to do is to create a separate SMTP proxy for each mail server (all within the same NST instance) and have it listen to a unique IP/port. Remember to change the MX record and/or your firewall/router configuration to make sure that incoming SMTP traffic is redirected to the corresponding IP/port.
